

TLE4929C-XHA

Universal Speed Sensor

Applications

The TLE4929C-XHA is an active Hall sensor ideally suited for crankshaft applications and similar industrial applications, such as speedometer or any speed-sensor with high accuracy and low jitter capabilities.

Features

- Measures speed and position of tooth/pole wheels
- Switching point in middle of the tooth enables backward compatibility
- Magnetic stray-field robustness due to differential sensing principle
- Direction detection and Stop-Start-Algorithm
- Programmable switching threshold for additional accuracy
- Hybrid-Algorithm keeps TLE4929C-XHA calibrated during electric drive

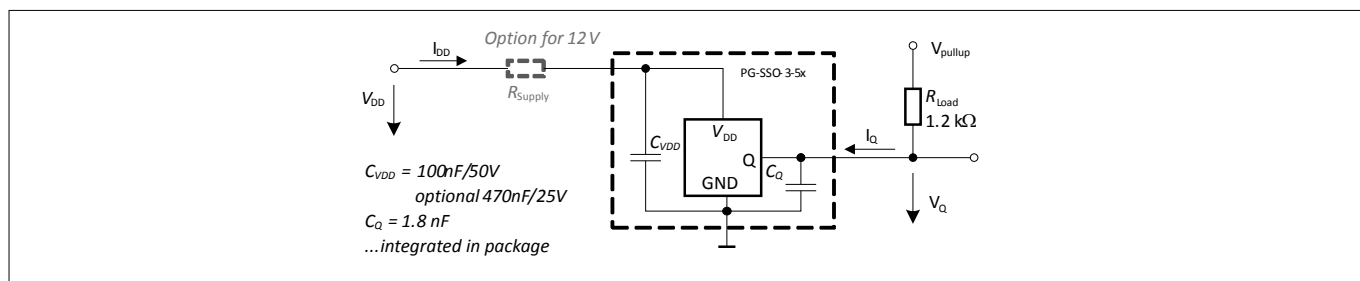

Figure 1 Typical Application Circuit

Description

The TLE4929C-XHA comes in a RoHS compliant three-pin package, qualified for automotive usage. It has two integrated capacitors on the lead frame (**Figure 1**). A pull-up resistor R_{Load} is mandatory on the output pin and determines the maximum current through the output transistor.

Table 1 Ordering Information

1 General Characteristics

1 General Characteristics

1.1 Absolute Maximum Ratings

Table 2 Absolute Maximum Ratings

Parameter	Symbol	Values			Unit	Note or Test Condition
		Min.	Typ.	Max.		
Voltages						
Supply voltage without supply resistor	V_{DD}	-16	–	18	V	continuous, $T_J \leq 175^\circ\text{C}$
		-18	–	27	V	max. 60s, $T_J \leq 175^\circ\text{C}$
Output OFF voltage	V_{Q_OFF}	-0.3	–	26.5	V	continuous, $T_J \leq 175^\circ\text{C}$
		-1.0	–	26.5	V	max. 1 h, $T_{Amb} \leq 40^\circ\text{C}$
Output ON voltage	V_{Q_ON}	-1.0	–	16	V	continuous, $T_{Amb} \leq 40^\circ\text{C}$
		-0.3	–	18	V	max. 1 h, $T_{Amb} \leq 40^\circ\text{C}$
		-0.3	–	26.5	V	max. 60 s, $T_{Amb} \leq 40^\circ\text{C}$
Temperatures						
Junction temperature range	T_J	-40	–	185	$^\circ\text{C}$	Exposure time: max. 10×1 h, $V_{DD} = 16$ V
Induction						
Magnetic field induction	$B_Z^{1)}$	-5	–	5	T	Magnetic pulse during magnet magnetization. Valid 10 s with $T_{ambient} \leq 80^\circ\text{C}$
ESD Resistivity						
ESD compliance	ESD_{HBM}	-6	–	6	kV	HBM ²⁾

Note: Stresses above the max values listed here may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Maximum ratings are absolute ratings; exceeding only one of these values may cause irreversible damage to the integrated circuit.

¹ Guaranteed by design.

² ESD susceptibility, HBM according to EIA/JESD 22-A114B.

1 General Characteristics

1.2 Operating Range

All parameters specified in the following sections refer to these operating conditions unless otherwise specified.

Table 3 General Operating Conditions

Parameter	Symbol	Values			Unit	Note or Test Condition
		Min.	Typ.	Max.		
Voltages						
Supply voltage without supply resistance R_s	V_{DD}	4.0	–	16	V	
Continuous Output Off voltage	V_{Q_OFF}	1.0	–	16	V	
Supply voltage power- up/down voltage ramp	dV_{DD}/dt	3.0	–	10000	V/ms	
Currents						
Supply current	I_{DD}	8.0	–	13.4	mA	
Continuous output On current	I_{Q_ON}	0.01	–	15	mA	$V_{Q_LOW} < 0.5 V$
Capacitance³⁾						
Capacitance between IC supply & ground pins for type TLE4929C-XHA-M18N	C_{VDD}	90	100	110	nF	
Capacitance between IC supply & ground pins for type TLE4929C-XHA-M38N	C_{VDD}	423	470	517	nF	
Output capacitance between IC output and ground pins	C_Q	1.62	1.8	1.98	nF	
Direction Detection						
Frequency range for direction detection	f_{Dir}	0	–	1800	Hz	For increasing rotational frequency
		0	–	1500	Hz	For decreasing rotational frequency
Programming						
Maximum No. of EEPROM programming cycles	N_{PROG}	–	–	100	n	
Magnetic Signal						
Magnetic signal frequency range	f	0	–	8000	Hz	Full accuracy
		8000	–	10000	Hz	10% degraded jitter
Dynamic range of the magnetic field of the differential speed channel	$DR_{mag_field_s}$	-120	-	120	mT	

³⁾ Specified at a room temperature, test condition at 25°C with 1 V at 1 kHz , temperature variation to be added

1 General Characteristics

Table 3 General Operating Conditions (continued)

Parameter	Symbol	Values			Unit	Note or Test Condition
		Min.	Typ.	Max.		
Dynamic range of the magnetic field of the direction channel	$DR_{mag_field_dir}$	-60	-	60	mT	
Static range of the magnetic field of the outer Hall probes in back-bias configuration	$SR_{mag_field_s_b}$	0	-	550	mT	No wheel in front of module / Offset-DAC-Compensation-range
Static range of the magnetic field of the outer Hall probes in magnetic encoder wheel configuration	$SR_{mag_field_s_p}$	-10	-	10	mT	Static absolute offset for pole wheel / Offset-DAC-Compensation-range / independent from Bit "POLE_WHEEL"
Static range of the magnetic field of the center Hall probe	$SR_{mag_field_dir}$	-100	-	450	mT	No wheel in front of module / Center-Offset-DAC-Compensation-range
Allowed static difference between outer probes	$SR_{mag_field_diff}$	-30	-	30	mT	No wheel in front of module
Magnetic differential field amplitude for full performance on stop-start	$\Delta B_{Speed_Stop,Start}$	9	-	-	mT _{pkpk}	No false pulses for temperature drift of ≤ 60 K during stop-start state. Tolerated change of speed-channel mean value ≤ 3 mT
		6	-	-	mT _{pkpk}	No false pulses for temperature drift of ≤ 40 K during stop-start state. Tolerated change of speed-channel mean value ≤ 2 mT
		4	-	-	mT _{pkpk}	No false pulses for temperature drift of ≤ 20 K during stop-start state. Tolerated change of speed-channel mean value ≤ 1.5 mT

Temperatures

Normal operating junction temperature	T_J	-40	-	175	°C	Exposure time: max. 2500 h at $T_J = 175^\circ\text{C}$, $V_{DD} = 16$ V
		-40	-	185	°C	Exposure time: max. 10×1 h at $T_J = 185^\circ\text{C}$, $V_{DD} = 16$ V, additive to other lifetime

1 General Characteristics

Table 3 **General Operating Conditions (continued)**

Parameter	Symbol	Values			Unit	Note or Test Condition
		Min.	Typ.	Max.		
Not operational lifetime	T_{no}	-40		150	°C	Without sensor function. Exposure time max 500 h @ 150°C; increased time for lower temperatures according to Arrhenius-Model, additive to other lifetime
Ambient temperature range for customer programming	T_{RDPROG}	15	25	130	°C	
Allowed temperature variations between engine stop and restart.	$\Delta T_{Stop,start}$	-	-	60	°C	Device powered continuously
Temperature compensation range of magnetic material	TC	-1900	-	0	ppm	Internal compensation of magnetic signal amplitude of speed signal

2 Electrical and Magnetic Characteristics

2 Electrical and Magnetic Characteristics

All values specified at constant amplitude and offset of input signal, over operating range, unless otherwise specified. Typical values correspond to $V_S = 5\text{ V}$ and $T_{\text{Amb.}} = 25^\circ\text{C}$.

Table 4 Electrical and Magnetic Parameters

Parameter	Symbol	Values			Unit	Note or Test Condition
		Min.	Typ.	Max.		
Voltage						
Output saturation voltage	$V_{Q\text{sat}}$	-	-	500	mV	$I_Q \leq 15\text{ mA}$
Clamping voltage V_{DD} -Pin	V_{DD_clamp}	42	-	-	V	leakage current through ESD-diode < 0.5 mA
Clamping voltage V_Q -Pin	V_{Qclamp}	42	-	-	V	leakage current through ESD-diode < 0.5 mA

Accuracy and Repeatability

⁵⁾ Smallest setting is not recommended for harsh environment: long tooth, long notch, vibration, run-out of target-wheel.

⁷⁾ Parameter not subject to productive test. Verified by laboratory characterization / design.

2 Electrical and Magnetic Characteristics

Table 4 Electrical and Magnetic Parameters (continued)

Parameter	Symbol	Values			Unit	Note or Test Condition
		Min.	Typ.	Max.		
Repeatability (Jitter)	Jitter ⁶⁾	-	-	0.015	°Crank	3 sigma, $\Delta B_{pkpk} = 20 \text{ mT}_{pkpk}$, FILTER_SELECT = 0
		-	-	0.025	°Crank	3 sigma, $\Delta B_{pkpk} = 9 \text{ mT}_{pkpk}$, measured on coil using sinus signal, $T_a = 150^\circ\text{C}$, $f = 8\text{kHz}$, FILTER_SELECT = 0
Number of wrong pulses at start-up	nStart ⁷⁾	-	-	0	n	Engine starts in continuous forward rotational direction
		0	-	1	n	Engine starts in continuous backward rotational direction
Number of wrong pulses after stop-start	nStop, start ⁷⁾	-	-	0	n	Multiple rotational direction changes > 6°Crank allowed
Maximum phase error	Phirunning ⁶⁾	-0.2	-	0.2	°Crank	$\Delta B_{Speed} > 9 \text{ mT}_{pkpk}$, signature excluded, accuracy on mentioned wheel in Figure 4
Maximum phase error after stop-start	Phistop, start ⁶⁾	-1.7	-	3.2	°Crank	Reduced phase accuracy only for first pulse after stop-start-state / signature excluded

Run Out Capabilities

Global run out (speed and direction channel)	Runout global ⁷⁾	1.0	-	1.67	-	Ratio = Amplitude(max)pkpk / Amplitude(min)pkpk
		1.0	-	2.5	-	Ratio = Amplitude(max)pkpk / Amplitude(min)pkpk . Reduced performance in Stop-Start-behavior.
Magnetic overshoot of signature region in speed signal. Magnetic overshoot from tooth to tooth (polepair to polepair)	Runout tooth, tooth ⁷⁾	0.8	1.2	1.6	-	Ratio = Amplitude(signature) / Amplitude(before/after). Valid for toothed target wheel.
		0.7	1.4	2.5	-	Ratio = Amplitude(signature) / Amplitude(before/after). Valid for magnetic target wheel.

Output Protocol Variants

Crankshaft without direction detection: Output follows profile of target wheel	-	-	-	-	-	Output “Q” changes state (“LOW” or “HIGH”) in the middle of the tooth / middle of the notch
--	---	---	---	---	---	---

⁶⁾ Parameter not subject to productive test. Verified by characterization in the laboratory based on jitter-measurement > 1000 falling edges.

⁷⁾ Parameter not subject to productive test. Verified by laboratory characterization / design.

2 Electrical and Magnetic Characteristics

Table 4 Electrical and Magnetic Parameters (continued)

Parameter	Symbol	Values			Unit	Note or Test Condition
		Min.	Typ.	Max.		
Crankshaft protocol with direction (option 1)	t_{fwd}	38	45	52	μs	$V_{Pullup} = 5 V, R_{Pullup} = 1.2 k\Omega (\pm 10\%), C_Q = 1.8 nF (\pm 15\%),$ valid between 50% of falling edge to 50% of next rising edge
	t_{bwd}	76	90	104	μs	
	$t_{standstill}$	152	180	208	μs	
Crankshaft protocol with direction (option 2)	t_{fwd}	38	45	52	μs	$V_{Pullup} = 5 V, R_{Pullup} = 1.2 k\Omega (\pm 10\%), C_Q = 1.8 nF (\pm 15\%),$ valid between 50% of falling edge to 50% of next rising edge
	t_{bwd}	152	180	208	μs	
	$t_{standstill}$	304	360	416	μs	
Crankshaft protocol with direction (option 3)	t_{fwd}	38	45	52	μs	$V_{Pullup} = 5 V, R_{Pullup} = 1.2 k\Omega (\pm 10\%), C_Q = 1.8 nF (\pm 15\%),$ valid between 50% of falling edge to 50% of next rising edge

	$t_{standstill}$	152	180	208	μs	
Crankshaft protocol with direction (option 4)	t_{fwd}	63	75	87	μs	$V_{Pullup} = 5 V, R_{Pullup} = 1.2 k\Omega (\pm 10\%), C_Q = 1.8 nF (\pm 15\%),$ valid between 50% of falling edge to 50% of next rising edge
	t_{bwd}	507	600	693	μs	
	$t_{standstill}$	304	360	416	μs	
Crankshaft protocol with direction (option 5)	t_{fwd}	18	22	26	μs	$V_{Pullup} = 5 V, R_{Pullup} = 1.2 k\Omega (\pm 10\%), C_Q = 1.8 nF (\pm 15\%),$ valid between 50% of falling edge to 50% of next rising edge
	t_{bwd}	38	45	52	μs	
	$t_{standstill}$	76	90	104	μs	
Crankshaft protocol with direction (option 6)	t_{fwd}	51	60	69	μs	$V_{Pullup} = 5 V, R_{Pullup} = 1.2 k\Omega (\pm 10\%), C_Q = 1.8 nF (\pm 15\%),$ valid between 50% of falling edge to 50% of next rising edge
	t_{bwd}	101	120	339	μs	
	$t_{standstill}$	304	360	416	μs	
Crankshaft protocol with direction (option 7)	t_{fwd}	25	30	35	μs	$V_{Pullup} = 5 V, R_{Pullup} = 1.2 k\Omega (\pm 10\%), C_Q = 1.8 nF (\pm 15\%),$ Valid between 50% of falling edge to 50% of next rising edge, Forward pulse is issued only once after rotational direction change. Further forward movement is issued as two edges per period according to a crankshaft-sensor without direction protocol. Details please find in Chapter 3.6 .
	t_{bwd}	51	60	69	μs	
Crankshaft protocol with direction (option 8)	t_{fwd}	76	90	104	μs	$V_{Pullup} = 5 V, R_{Pullup} = 1.2 k\Omega (\pm 10\%), C_Q = 1.8 nF (\pm 15\%),$ valid between 50% of falling edge to 50% of next rising edge
	t_{bwd}	114	135	156	μs	
	$t_{standstill}$	304	360	416	μs	

Note: The listed Electrical and magnetic characteristics are ensured over the operating range of the integrated circuit. Typical characteristics specify mean values expected over the production spread. If not other specified, typical characteristics apply at $T_{Amb} = 25^\circ C$ and $V_S = 5 V$.

3 Functional Description

3 Functional Description

3.1 Definition of the Magnetic Field Direction

The magnetic field of a permanent magnet exits from the north pole and enters the south pole. If a north pole is attached to the backside of the High End Crankshaft Sensor, the field at the sensor position is positive, as shown in **Figure 3**.

Figure 3 Definition of the Positive Magnetic Field Direction

3.2 Block Diagram

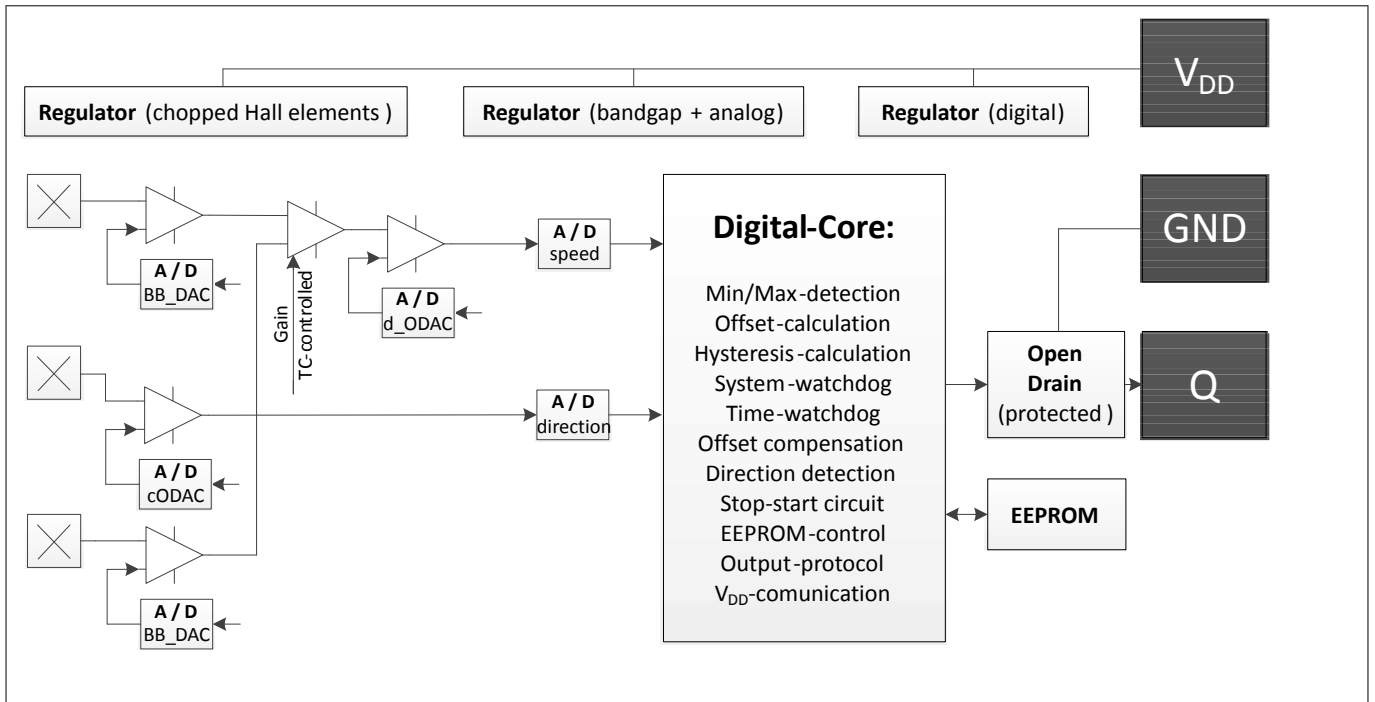

Figure 4 Block Diagram

3 Functional Description

3.3 Basic Operation

The basic operation of the TLE4929C-XHA is to transpose the magnetic field produced by a spinning target wheel into speed pulses with directional information at the output pin. The pulse width indicates forward or backward direction information and can be adjusted in EEPROM-options. It is also possible to parameterize output switching without direction information like it is requested for differential CAM-shaft sensors. The correspondence between field polarity and output polarity can be set according to the application needs as well. By definition a magnetic field is considered as positive if the magnetic North Pole is placed at the rear side of the sensor, see [Figure 3](#).

For understanding the operation five different phases have to be considered:

- Power-on phase
 - starts after supply release
 - lasts $t_{\text{power-on}}$ (power-on time)
 - IC loads configuration and settings from EEPROM and initializes state machines and signal path
 - output is locked HIGH
- Initial phase ([Figure 5](#) "Uncalibrated mode")
 - starts after Power-on phase
 - lasts one clock cycle
 - IC enables output switching, extrema detection and threshold adaption
- Calibration phase 1 ([Figure 5](#) "Uncalibrated mode")
 - starts after Initial phase
 - lasts until the sensor has observed 3 magnetic edges (maximum 4 magnetic edges) and is able to perform the most likely final threshold update needed for transition to "Calibration Phase 2".
 - IC performs fast adaptation of the threshold according to the application magnetic field
 - initial and second switching (uncalibrated mode) of the output is performed according to the detected field change of the differential magnetic field
 - length of the output-pulse is derived from the center Hall probe (direction signal) sampled at the zero-crossing of the differential outer Hall probes (speed signal)
 - length of the very first pulse is "forward-pulse" according to chosen protocol in EEPROM (direction information is not valid at this time)
- Calibration phase 2
 - starts after "Calibration Phase 1"
 - lasts until the sensor has reached final offset-calibration which is minimum 5 teeth / maximum 64 teeth (pole-pairs) according to chosen algorithm in EEPROM
 - IC performs slow and accurate adaptation of the threshold according to the application magnetic field
 - output switching (calibrated mode) is performed according to magnetic zero-crossing of the differential magnetic field
 - length of the output-pulse is derived from the center Hall probe (direction signal) sampled at the zero-crossing of the differential outer Hall probes (speed signal)
- Running phase
 - starts after "Calibration Phase 2"
 - lasts indefinitely if no special condition is triggered (see [Chapter 3.8](#))
 - performs a filter algorithm in order to maintain superior phase accuracy and improved jitter
 - output switches according to the threshold value, according to the hidden hysteresis algorithm and according to the chosen output-protocol

3 Functional Description

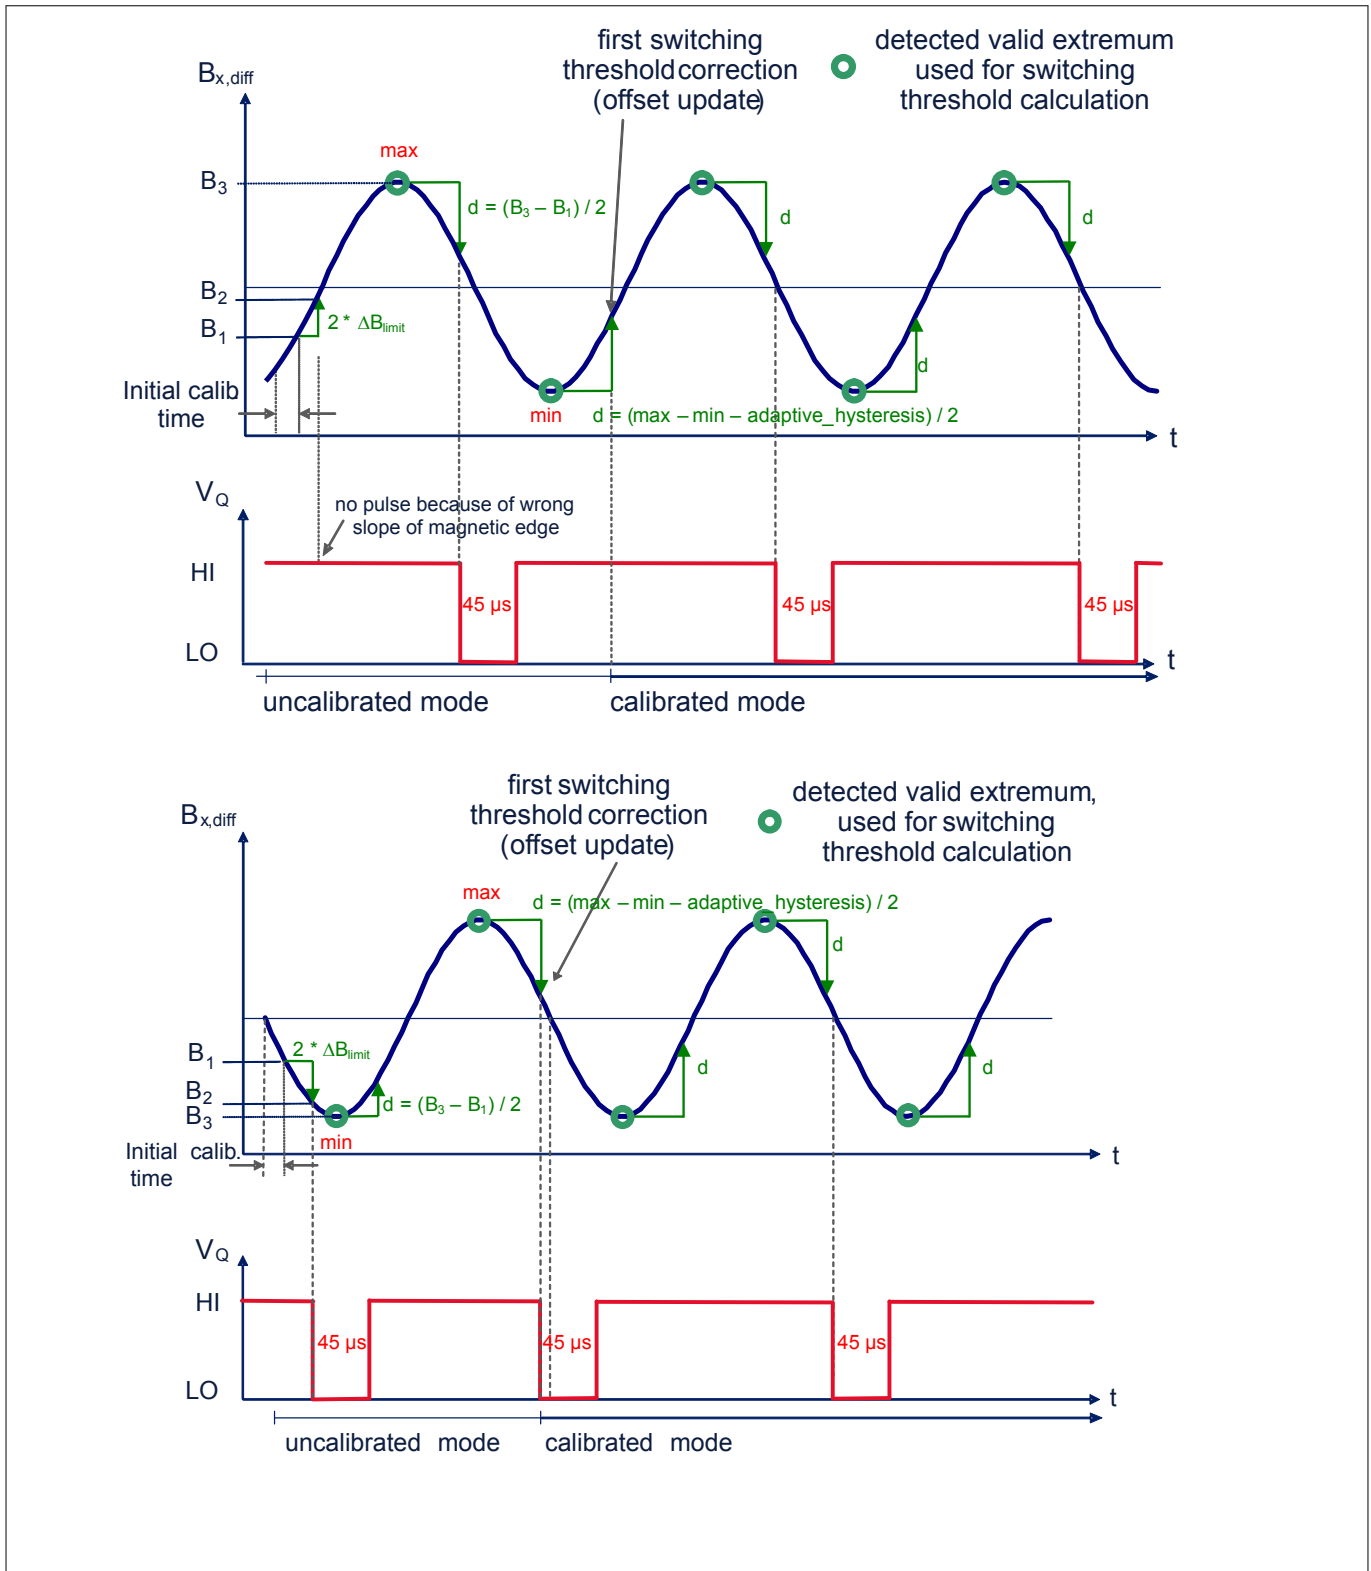

Figure 5 Operating Phases - Power-on to Running Phase

3 Functional Description

3.3.1 Power-on Phase

The operation in Power-on Phase is to refresh the trimming coefficients and algorithm settings from the EEPROM and to allow the signal path to stabilize.

If an unrecoverable error is found at EEPROM refresh, the output will remain locked HIGH during the entire operation.

3.3.2 Initial Phase

The magnetic field is measured by three chopped Hall probes. From the outer Hall probes located at a distance of 2.5 mm a differential magnetic field is measured which is named “speed” in this datasheet. From the center Hall probe the “direction” signal is derived. Both signals are converted to a digital value via an ADC.

3.3.3 Calibration Phase

The adaptation of the threshold to the magnetic field is performed in Calibration Phase. This adaptation is done based on the field values set by teeth and notches (or based on poles on the pole wheel). These variations in the magnetic field are followed by a local extrema detection state machine in the IC. During Calibration Phase the IC permanently monitors the magnetic signal. First and second switching is performed when the speed-path recognized a certain change of magnetic field and the polarity meets the switching criterion derived from the EEPROM. The third and further pulse of the output is performed at “zero-crossing” of the speed path. “Zero crossing” is the 50%-value between detected minimum and detected maximum - also known as “offset”.

3.3.4 Running Phase

According to the chosen algorithm in EEPROM an average of 5 to 58 pulses is used to do an offset-calculation and an offset-update.

The following rules have to be verified before applying a computed update to the threshold register:

- Compatibility between threshold update sign and magnetic edge
- Threshold update has to be large enough not to be discarded (`minimum_update`)
- Threshold update is limited to a maximum value based on field amplitude and on comparison with absolute field value (`maximum_update`)
- Computed threshold update is always halved before being applied
- Threshold update is filtered to discourage consecutive updates in opposite direction (`consecutive_upd_req`)

Typically the offset is updated after one complete revolution of the target wheel, which is effectively 58 teeth.

3 Functional Description

Table 5 Available offset update algorithm to be chosen in EEPROM

Parameter	Symbol	Values			Unit	Note or Test Condition
		Min.	Typ.	Max.		
Offset update algorithm	58 teeth	-	58	-	-	one revolution of a 60-2 target
	56 teeth	-	56	-	-	one revolution of a 60-2-2 teeth /pole-pair target
	34 teeth	-	34	-	-	one revolution of a 36-2 teeth /pole-pair target
	32 teeth	-	32	-	-	one revolution of a 32-teeth /pole-pair target
	5 times the same sign for offset-update	5	-	-	-	suggested for wheels with different number of teeth or for large run-out.

3.3.5 Averaging Algorithm

To calculate the threshold within the running phase, valid maxima and minima are averaged to reduce possible offset-updates. Each offset-update gives an increased jitter, which has to be avoided.

3.3.6 Direction Detection

Direction is calculated from the amplitude-value of direction-signal sampled at zero-crossing of speed-channel. For each pole-pair or pair of tooth and notch two digital values are generated for detecting the direction. Subtracting the second value from the first value the direction is determined by its sign. According to EEPROM-setting a positive sign is either direction forward or direction backward.

Table 6 EEPROM-options for polarity and direction

EEPROM EDGE_POLAR	EEPROM FORWARD_DEF	Function
0	0	Forward-pulse is issued when wheel rotates from pin 1 to pin 3. Falling edge of output-pulse occurs at middle of the notch.
0	1	Forward-pulse is issued when wheel rotates from pin 3 to pin 1. Falling edge of output-pulse occurs at middle of the tooth.
1	0	Forward-pulse is issued when wheel rotates from pin 1 to pin 3. Falling edge of output-pulse occurs at middle of the tooth.
1	1	Forward-pulse is issued when wheel rotates from pin 3 to pin 1. Falling edge of output-pulse occurs at middle of the notch.

3 Functional Description

Figure 6 Direction Detection Principle: TLE4929C-XHA-M18N issues forward-pulses at each middle of tooth

Figure 7 Direction Detection Principle: Rotation Direction Forward And Backward

3 Functional Description

3.3.7 Direction Detection Threshold

To recognize a change in rotational direction of the target wheel a threshold (**Figure 8**) is used. The peak-to-peak signal of direction is averaged over the last 5 teeth and is used as 100% value. Whenever a new minimum or a new maximum is measured, a threshold of 25% is calculated.

Figure 8 Direction Threshold Level

At a constant direction the next sample-point is expected to have another 100% signal amplitude. In the case of a rotational direction change the same value as before is expected. To distinguish between these two cases a virtual threshold of 25% is taken into account. Using EEPROM these 25% can be programmed to 12.5% (direction change criterion).

3 Functional Description

3.4 Hysteresis Concept

Figure 9 Hidden Hysteresis in protocol-variant without direction detection

The preferred switching behavior for crankshaft application in terms of hysteresis is called hidden adaptive hysteresis. For reason of long notches or long teeth there is the EEPROM possibility to go for visible hysteresis as well. Another EEPROM possibility is fixed hysteresis, which allows robustness against metallic flakes attached by the back-bias-magnet.

Hidden adaptive hysteresis means, the output always switches at the same level, centered between upper and lower hysteresis. These hysteresis thresholds needs to be exceeded and are used to enable the output for the next following switching event. For example, if the differential magnetic field crosses the lower hysteresis level, then the output is able to switch at the zero crossing. Next following upper hysteresis needs to be exceeded again in order to enable for the next switching. Furthermore, the function of half hysteresis maintains switching whenever the upper hysteresis level is not exceeded, but the lower hysteresis level is crossed again, then the output is allowed to switch, so that no edge is lost. However, this causes additional phase error, see [Figure 9](#).

Doing an adaptive hysteresis gives advantage at small airgap (large signal) to have big hysteresis. Compared with fixed hysteresis a small vibration cannot cause additional switching. According [Figure 10](#) the adaptive hysteresis is calculated as 25% of the differential Speed-signal peak to peak. The minimum hysteresis is derived from EEPROM-setting.

3 Functional Description

3 Functional Description

3.5 Rotational Direction Definition and Edge Polarity Definition

TLE4929C-XHA has EEPROM-options to change the position of the output-protocol. In the application the switching point is either the middle of the tooth or the middle of the notch (magnetic encoder wheel: middle of north pole or middle of south pole). From magnetic point of view it is zero crossing of the differential speed signal: Either rising edge or falling edge. The EEPROM-Bit “EDGE_POLAR” parametrizes the sensor to one of the edges.

In addition there is an option to issue “forward”-pulses either in CW rotational direction or CCW rotational direction: “FORWARD_DEF”.

Both EEPROM-bits are independent from each other.

Figure 11 Signal output in setting “EDGE_POLAR = 0” and “FORWARD_DEF” = 0

3 Functional Description

3.6 New crank protocol: forward on edges / backward on PWM

According to specification of a major OEM there is a new protocol implemented.

In forward rotational direction the TLE4929C-XHA behaves like a crankshaft-sensor without direction detection and issues one falling and one rising edge per magnetic period of the target wheel. This includes the advantage to have double number of position information for each rotation of the wheel. On a typical crankwheel consisting of 58 teeth the position is transferred 116 times.

Using bit "OEM_FW_START" defines the start-up and calibration behavior.

3.7 System Watchdog

The system watchdog is monitoring following parts in the digital core and at the output:

- Finding valid maxim in the speed signal
- Finding valid minim in the speed signal
- Finding valid zero-crossing of the speed signal
- Monitoring the output switching

As long the speed signal and the corresponding output switching is fine the system watchdog will reset itself automatically at every output-switching. As soon the system watchdog detects valid maximum, valid minimum and valid zero-crossing without a switching event at the output, the system watchdog will increase its counter. Switching of the output sets the counter to zero. When the counter reaches its limit the offset will be reset.

The advantage of this system watchdog is to avoid "flat line" behavior at the output. Once there happened a massive event in the sensing system (i.e. hit on the tooth, sudden air gap jump, ...), the TLE4929C-XHA is able to recover itself. The system watchdog can be enabled by EEPROM setting "WATCH_DOG_EN".

3.8 Stop Start Watchdog

The Stop Start Watchdog allows TLE4929C-XHA to stay calibrated during stand-still of the target wheel and a possible temperature-drift of 60K. It can be enabled by EEPROM-option.

Basically the Stop Start watchdog is a time-out of 1.4 seconds. After 1.4 seconds time out between two zero crossing of the speed channel (crankshaft wheel stopped) the Stop Start Watchdog will enter active state. No output switching is enabled during active watchdog state. After a signal-change in speed channel above DNC within 1.4 seconds (crankshaft wheel rotates) the TLE4929C-XHA will use known signal-amplitude and perform output-switching with the new switching threshold at the new temperature.

At standstill of the target wheel the stop start watchdog will enable TLE4929C-XHA to not issue any wrong pulse at the output:

- No additional pulses
- No missing pulses
- No false rotational direction information

Combining the System Watchdog and the Stop Start Watchdog an immunity to vibration can be added to the Stop-Start-behavior.

Further details are available on request.

3.9 Time Watchdog

The Time Watchdog allows TLE4929C-XHA to go to uncalibrated mode during stand-still of the target wheel at power on. It can be enabled by EEPROM-option and is similar to Stop Start Watchdog. A unintentional calibration will be suppressed during start up due to vibration.

3 Functional Description

Basically the Time watchdog is a time-out of 1.4 seconds. It observes the time between two consecutive edges (rising to falling or falling to rising) of the output. When the time is longer than 1.4 seconds the Time Watchdog gets active.

In active mode of Time watchdog the behavior is similar as in Stop Start Watchdog. It is considered to have either stand-still or very slow vibration. In order to get a fast startup without missing or wrong pulses at the output the offset of the speed-channel is set to “uncalibrated mode”. This means full offset-update is allowed after starting with switching on DNC. The output will switch at zerocrossing after the first offset-update.

The Stop Start watchdog cannot be activated during the Time Watchdog is activated.

The Time Watchdog supports all crankshaft-protocol options and is active for the slow algorithm (ADAPT_FILT=0) until the first update after one complete revolution is done. As long as the Time Watchdog is active the Stop Start Watchdog is disabled.

3.10 Hybrid Vehicle Watchdog

The Hybrid Vehicle Watchdog allows TLE4929C-XHA to detect the stopped crankshaft during electric drive. Calibration is disabled during electric drive of the hybrid car. When combustion engine is started again the calibration is allowed to follow the update rules again. A wrong calibration on a vibrating crankshaft is avoided. The state “Running Phase” of the TLE4929C-XHA ([Chapter 3.3.4](#)) has to be entered once to take advantage of this feature.

This mechanism can be enabled or disabled by EEPROM-Bit “WATCHDOG_HYBRID”.

3.11 Programmable Adaptive Switching Threshold (K-FACTOR)

To increase phase accuracy of TLE4929C-XHA the known feature from CAM application was implemented. In certain circumstances like the geometry of the trigger wheel the switching threshold of 50% between magnetic minimum and magnetic maximum of the speed channel is not the best choice. To offer better accuracy 8 settings between 39% and 63% are possible to program. The factor is known as k-factor.

The calculation of the adaptive programmable switching threshold is done as following:

Switching Threshold = $B_{min} + (B_{max} - B_{min}) * k$

If the K-FACTOR is different than 50% only hidden hysteresis switching is possible.

3.12 High Speed Mode

The high speed mode can be switched on or off by EEPROM bit “HIGH_SPEED”. Switched to state “off” the TLE4929C-XHA behaves as described. Switched to state “on” the TLE4929C-XHA stops direction detection above a certain input signal frequency of typically 1.8 kHz and continues with the last detected direction. To switch to high speed mode the frequency has to be measured two times. Coming from high frequencies the direction detection is enabled again going below the frequency threshold of 1.5 kHz.

3.13 Serial Interface

The serial interface is used to set parameter and to program the sensor IC, it allows writing and reading of internal registers. Data transmission to the IC is done by supply voltage modulation, by providing the clock timing and data information via only one line. Data from the IC are delivered via the output line, triggered by as well clocking the supply line. In normal application operation the interface is not active, for entering that mode a certain command right after power-on is required.

4 EEPROM Description

4 EEPROM Description

Several options of TLE4929C-XHA can be configured via an EEPROM setting to optimize the sensor algorithm to the individual target wheel and application requirements. The EEPROM memory is organized in 2 customer lines, whereas each line is composed of 16 data bits and additional 6 bits for error detection and correction, based on ECC (Error Correction Code). For more detailed information about EEPROM access and programming an EEPROM Programming manual is available.

5 Package Information

5 Package Information

Pure Nickel plating is used. The product is RoHS (Restriction of Hazardous Substances) compliant and marked with letter G in front of the data code marking and contains a data matrix code on the rear side of the package (see also information note 136/03). Please refer to your key account team or regional sales if you need further information.

The specification for soldering and welding is defined in the latest revision of application note “Recommendation for Handling and Assembly of Infineon PG-SSO Sensor Packages”.

Position tolerance of sensing elements has CpK > 1.67 in both dimensions.
